Today, after a long process of seeking for dsl under python I've found one interesting gist on github where the author wrote a little module which provides fast and short describing html-templates and rendering them.

I've analized this code and understood that this snippet doesn't support working in thread and after some having a think I've realized this feature using threading module. Context information is stored in dictionary, where key-value is formed using thread name-attribute. Module threading supports naming threads with same names and a programmer must be carefull using this code, but in most cases threads are automatically named using template "MainThread,Thread-<1> .... Thread-<N>", so at most it mught be usefull for somebody :)

There is a few examples of using it:
